

Get Wazuh Manager + ELK stack running on Docker on the host machine

- Pre-download Docker images first thing in the morning:
 - wazuh/wazuh-manager, wazuh/wazuh-dashboard, elasticsearch, kibana

Screenshot 1: Wazuh SIEM Dashboard - Successfully Deployed and Accessible

This screenshot confirms the Wazuh SIEM dashboard is live and accessible at <https://localhost:443> on the host machine. The dashboard was deployed using the official Wazuh Docker Compose single-node setup (version 4.7.5). It displays key SOC metrics including Total Agents, Active Agents, Disconnected Agents, Pending Agents, and Never Connected Agents - all showing 0 at this stage as no VM agents have been enrolled yet. The available modules visible on the dashboard include Security Events, Integrity Monitoring, Policy Monitoring, System Auditing, and Security Configuration Assessment. The yellow warning message stating No agents were added to this manager confirms the system is fully operational and awaiting agent connections from VM3. Tool justification: Wazuh + ELK was selected because it is fully Docker-deployable with zero external internet dependency, making it compatible with SRM network constraints.

Screenshot 2: Docker Desktop - All Three Wazuh Containers Running Successfully

This screenshot shows Docker Desktop with the complete Wazuh single-node stack running on the host machine. The Containers panel shows all services active under the single-node group with a green status indicator. The system is consuming 1.63% CPU out of 1200% available (12 CPUs) and 1.64 GB out of 7.42 GB RAM, confirming the stack is running efficiently without overloading the host. The Engine running indicator at the bottom left confirms Docker is fully operational. The three containers deployed are: wazuh.manager (handles log collection and analysis), wazuh.indexer (Elasticsearch-based data storage and indexing), and wazuh.dashboard (Kibana-based web interface for visualisation). All were deployed using a single docker compose up -d command from the official Wazuh v4.7.5 Docker Compose configuration. Disk usage is 7.52 GB out of 1006.85 GB, well within safe operating limits.

This screenshot captures two critical CMD outputs. The first shows the successful completion of `docker compose pull`, confirming all three Wazuh Docker images were downloaded: `wazuh/wazuh-manager:4.7.5` (pulled in 546.1 seconds), `wazuh/wazuh-indexer:4.7.5` (pulled in 1102.7 seconds), and `wazuh/wazuh-dashboard:4.7.5` (pulled in 802.6 seconds), totalling approximately 3 to 4 GB of data. Images were pre-downloaded early in the day to avoid network congestion later. The second output shows `docker compose up -d` completing successfully, with all 14 persistent Docker volumes created (for configuration, logs, certificates, and data storage) and all three containers started: `single-node-wazuh.manager-1`, `single-node-wazuh.indexer-1`, and `single-node-wazuh.dashboard-1`. This completes the full SIEM layer deployment for Day 1 of the Mini Sentries Hackathon.
